Abstract The purpose of this study was to determine whether there were differences in the prevalence of risk factors for low back pain between two groups of nurses. One group consisted of nurses who had been employed by their current employer for less than five years and the other group consisted of nurses who had been employed by their current employer for five or more years. A questionnaire was mailed to all nurses in each group. The questionnaire asked about demographic information, work-related variables, and self-reported symptoms. Results showed that the prevalence of low back pain was higher among nurses who had been employed by their current employer for five or more years compared to those who had been employed for less than five years. This finding suggests that long-term employment may be associated with a higher prevalence of low back pain.
